Grammar Prompting for Domain-Specific Language Generation with Large Language Models

{bailinw,yoonkim}@mit.edu,{wangzi, xuezhiw, yuancao, rif}@google.com

Abstract

Large language models (LLMs) can learn to perform a wide range of natural language tasks from just a handful of in-context examples. However, for generating strings from highly structured languages (e.g., semantic parsing to complex domain-specific languages), it is challenging for the LLM to generalize from just a few exemplars. We explore grammar prompting as a simple approach for enabling LLMs to use external knowledge and domain-specific constraints, expressed through a grammar expressed in Backus-Naur Form (BNF), during incontext learning. Grammar prompting augments each demonstration example with a specialized grammar that is minimally sufficient for generating the particular output example, where the specialized grammar is a subset of the full DSL grammar. For inference, the LLM first predicts a BNF grammar given a test input, and then generates the output according to the rules of the grammar. Experiments demonstrate that grammar prompting can enable LLMs to perform competitively on a diverse set of DSL generation tasks, including semantic parsing (SMCalFlow, Overnight, GeoQuery), PDDL planning, and even molecule generation (SMILES).

1 Introduction

Prompting large language models (LLMs) with demonstrations and/or natural language instructions has been shown to be an effective approach for surfacing their myriad capabilities acquired through pretraining [9]. This approach is however inadequate for applications where the task specifications cannot be fully delineated through just a handful of exemplars, for example in semantic parsing where an LLM must translate a natural language utterance to an executable program in a domain-specific language (DSL). DSLs often incorporate domain-specific abstractions and semantics that are difficult to characterize via just a few demonstrations. And unlike general-purpose programming languages, DSLs are by definition specialized and thus unlikely to have been encountered often enough (or at all) during pretraining for the LLM to acquire its full syntax.

How can we draw on the few-shot learning capabilities of LLMs for applications where it must generate strings in structured output space that is substantially different from those seen during pretraining? This work explores $grammar\ prompting$ as a simple approach for data-efficient generation of structured languages where an output string in the language can be derived through a series of symbolic manipulations. We exploit the fact that constraints over a structured output space can often be succinctly described by a context-free grammar in Backus–Naur Form (BNF), a commonly-used metalanguage for defining a language's syntax. Grammar prompting augments each in-context example (x,y) with a specialized BNF grammar G[y] that is minimally sufficient for generating y. Given a new input, the LLM first predicts the BNF grammar and then generates the answer conditioned on the grammar.

Grammar prompting follows the recent line of work which enhances the few-shot reasoning capabilities of LLMs by interleaving intermediate "reasoning" steps between each in-context input and output [49, 24, 80, 76, 70]. The key difference in our approach is that the intermediate variable is in

the form of a formal grammar rather than in natural language, which focuses on eliciting the symbolic manipulation capabilities of LLMs. The use of a formal grammar moreover makes it possible to impose constraints during incremental decoding such that syntactic validity is guaranteed. Finally, unlike chain-of-thought-style prompts [80] which typically require manual verbalization of the intermediate reasoning steps, in our approach the specialized grammar G[y] can be derived automatically by parsing the output y with the full (unspecialized) DSL grammar.

We apply grammar prompting to various domain specific languages for semantic parsing (SM-CalFlow, Overnight, GeoQuery), AI planning (PDDL), and molecule generation (SMILES), and find that it can meaningfully improve upon standard prompting baselines in the few-shot setting.

2 Background and Motivation

2.1 Domain-Specific Languages

Let Σ^* be the set of all finite strings over an alphabet Σ , and further let $D \subseteq \Sigma^*$ be a domain-specific language (DSL) for an application of interest. Given an input x (e.g., a natural language command) we are interested in generating $y \in D$ (e.g., a program in a DSL fulfilling the command), as shown by the following calendar assistant example from SMCalFlow [6]:

```
x: Add meeting with Jean's manager on Wednesday at 3PM.
```

```
y: CreateEvent(& (start_? WednesdayNumberPM(3))(attendee_? FindManager(Jean)))
```

DSLs are crafted by experts who use their domain-specific knowledge to incorporate higher-level abstractions than are typically found in general-purpose programming languages. We assume access to an expert-defined grammar G that fully specifies the DSL's syntax. As is the case with many DSLs, we further assume that G is a context-free grammar in Backus–Naur Form (BNF). See Figure 1 for a simple example adapted from SMCalFlow [6]. Letting L(G) be the language generated by G, we have $D \subseteq L(G) \subseteq \Sigma^*$ (not all syntactically valid programs are semantically valid).

2.2 Few-shot Learning with Large Language Models

In-context learning with large language models (LLMs) has been shown to be an effective approach for few-shot learning [9]. Under this approach, a pretrained LLM is conditioned on N demonstration examples $(\boldsymbol{x}^{(i)}, \boldsymbol{y}^{(i)})_{i=1}^N$ followed by a test example \boldsymbol{x} , and the output is given by decoding from the prompted LLM, i.e., $P_{\text{LLM}}(\boldsymbol{y} \mid \boldsymbol{x}, (\boldsymbol{x}^{(i)}, \boldsymbol{y}^{(i)})_{i=1}^N)$. The demonstration examples can be optionally preceded by natural language instructions to further improve performance or even enable zero-shot learning [79, 60]. Recent work has additionally shown that interleaving natural language verbalizations of intermediate reasoning steps between each $\boldsymbol{x}^{(i)}$ and $\boldsymbol{y}^{(i)}$ can greatly improve few-shot performance on complex reasoning tasks [49, 80, 76, 70, 15].

The effectiveness of few-shot in-context learning depends on how useful the implicit knowledge acquired through pretraining is for the task, and also on how effectively the task specifications can be conveyed through the demonstrations. Few-shot generation of strings of a DSL, where the structured nature of combinatorial output space (i.e., the DSL grammar *G*) cannot be adequately captured through just a handful of demonstrations, remains challenging for LLMs.

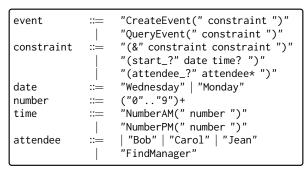

Figure 1: A simple BNF grammar for a calendar DSL.

3 Grammar Prompting

Grammar prompting exploits the fact that while the actual strings of a DSL may not have been encountered frequently enough (or at all) during pretraining for the LLM to implicitly acquire its syntax, the LLM will likely have encountered many instances of *metalanguages*—i.e., languages used to describe other languages. BNF grammars are a standard metalanguage for specifying the a language's syntax, and is expected to occur in the LLM training corpus with some frequency (e.g., in computer science textbooks). We thus focus on using BNF grammars for few-shot DSL generation.

```
LLM Prompt
You are an expert programmer, and you need to write a program for the given natural language guery.
First, you should write a grammar that contains all the necessary BNF rules. Then, you should write pro-
grams that conform to your predicted rules.
(optional) G:
                [BEGIN RULES]
                                                        [END RULES]
oldsymbol{x}^{(1)}: find the meeting on Wednesday with Bob and Carol
G[y^{(1)}]:
                                     "QueryEvent(" constraint ")"
                                     "(&" constraint constraint ")"
                   constraint
                                     "(start_?" date ")"
                                     "(attendee_?" attendee attendee ")"
                                     "Wednesday"
                  date
                               ::=
                   attendee
                                     "Bob" | "Carol"
 ^{(1)}: QueryEvent(& (start_? Wednesday)(attendee_? Bob Carol))
...
{m x}: Add meeting with Jean's manager on Wednesday at 3PM
```

```
LLM Output
                    event
                                        "CreateEvent(" constraint ")"
\widehat{G}
                                        "(&" constraint constraint ")"
                    constraint
                                        "(start_?" date time ")"
                                        "(attendee_?" attendee ")"
                                        "Wednesday"
                    date
                                  ::=
                                        "NumberPM(3)"
                    time
                                  ::=
                                        "FindManager(" attendee ")" | "Jean"
\hat{y}: CreateEvent(& (start_? Wednesday NumberPM(3))(attendee_? FindManager(Jean)))
```

Figure 2: Example of grammar prompting for a calendar DSL. We interleave the minimal specialized grammar $G[\boldsymbol{y}^{(i)}]$ between the demonstrations $\boldsymbol{x}^{(i)}$ and $\boldsymbol{y}^{(i)}$. During decoding, the LLM first predicts the specialized grammar \widehat{G} , and then predicts the program $\widehat{\boldsymbol{y}}$ conditoned on \widehat{G} . The blue portion is not part of the actual prompt and only shown for illustrative purposes.

```
Let G = \bigcup_{j=1}^{M} \{r_j\} be an extended BNF grammar where each rule r_j is of the form 
 \{\text{symbol}\} ::= \{\text{expr}_1\} \mid \{\text{expr}_2\} \mid \ldots
```

Here <symbol> is a nonterminal symbol and each <expr $_1>$ is a sequence of nonterminal and terminal symbols. A straightforward approach for incorporating a BNF grammar during in-context learning is to simply prepend the string representation of the full grammar G to the demonstration examples. However in preliminary experiments, we found that simply prepending the grammar to standard prompts along with an instruction to use the grammar did not yield any improvements. 2

3.1 Specialized Grammars

We instead propose to use *specialized grammars* to enable LLMs to make better use of domain-specific knowledge and constraints. A specialized grammar $G' \subseteq G$ is a grammar obtained from taking a subset of the rules of the full grammar G. We further define a *minimal specialized grammar* of \boldsymbol{y} to be the smallest BNF grammar (as measured by number of rules) such that $\boldsymbol{y} \in L(G[\boldsymbol{y}])$ (i.e., $\forall r \in G[\boldsymbol{y}], \ \boldsymbol{y} \notin L(G[\boldsymbol{y}] \setminus \{r\})$). Note that the minimal specialized grammar may not be unique due to the potential instantiation of abstract BNF rules (i.e., extended BNF rules). In most applications we consider the rules of the minimal specialized grammar will be concrete. See appendix A.1 for further details.

¹For brevity we forgo the formal tuple-based definition of G and instead define G to be equivalent to its context-free rules. We also freely go back and forth between this set definition of G and its string representation.

 $^{^2}$ However, when combined with specialized grammars we did observe small improvements by appending the full DSL grammar to the instructions. Hence, for all experiments where G is small enough (GeoQuery, Overnight-B, SMILES), we include G as part of the instruction. See Figure 2.

³For instance, the expression "(attendee_?" attendee* ")" depicted in Figure 1 implicitly defines all occurrences of attendee greater than 1. If this expression is incorporated into a program, either the concrete rule "(attendee_?" attendee ")" or the original rule could be included in the minimal specialized grammar.

Grammar prompting feeds a sequence of $(x^{(i)}, G[y^{(i)}], y^{(i)})_{i=1}^N$ along with x as a prompt to an LLM. For inference we first obtain the specialized grammar with an (approximate) $\arg\max$ decoding

$$\widehat{G} = \operatorname*{arg\,max}_{G' \subseteq G} \ P_{\mathrm{LLM}}(G' \,|\, \boldsymbol{x}, (\boldsymbol{x^{(i)}}, G[\boldsymbol{y^{(i)}}], \boldsymbol{y^{(i)}})_{i=1}^{N}).$$

We then obtain the program conditioned on \widehat{G} ,

$$\widehat{\boldsymbol{y}} = \underset{\boldsymbol{y} \in L(\widehat{G})}{\operatorname{arg\,max}} \ P_{\operatorname{LLM}}(\boldsymbol{y} \,|\, \widehat{G}, \boldsymbol{x}, (\boldsymbol{x}^{(i)}, G[\boldsymbol{y}^{(i)}], \boldsymbol{y}^{(i)})_{i=1}^N).$$

We discuss how to perform constrained decoding with $G \subseteq G$ and $y \in L(\widehat{G})$ in the next section. Grammar prompting views DSL program generation as a grammar specialization process where given a natural language specification x, a set of production rules is selected from G, and then a program y is deduced according to the selected rules. Grammar prompting can also be viewed as an instance of chain-of-thought prompting [49, 80] where the intermediate thought is in the form of a formal grammar. However, unlike typical chain-of-thought prompting where the answer is (usually) deterministic given the intermediate reasoning steps, in our case there is still some uncertainty with respect to \widehat{y} given \widehat{G} (e.g., $L(\widehat{G})$ could still be infinite).

3.2 Constrained Decoding

The use of a formal grammar as an intermediate variable makes it possible to enforce grammatical constraints during autoregressive LLM decoding. We first discuss how we enforce the constraint $y \in$ L(G). One approach to constrained decoding is to use \widehat{G} to obtain a left-to-right Earley parser [17] and only decode from valid continuations at each decoding step. However this simple strategy poses several practical challenges when working with API-only LLMs. For one, a valid terminal continuation in \widehat{G} may consist of multiple BPE tokens. More seriously, while we can sample a valid continuation at each time step by disallowing invalid tokens,⁴ since the set of valid continuations changes at each time step, this strategy would require calling the LLM API at each time step

Algorithm 1 Earley-based Constrained Generation

```
Input: Test input x, predicted grammar \widehat{G}
Output: Program y \in L(\widehat{G})
        1: t \leftarrow 0, \hat{\boldsymbol{y}}^{(0)} \leftarrow \epsilon

    initialize to empty string

      2: while True do
                                              t \leftarrow t + 1 > unconstrained greedy decoding
                                              \bar{\boldsymbol{y}} \leftarrow \operatorname{decode}\left(P_{\operatorname{LLM}}(\cdot \,|\, \boldsymbol{x}, \widehat{G}, \hat{\boldsymbol{y}}^{(t-1)}, \dots)\right)
                                              \hat{\pmb{y}}^{(t)} \leftarrow \hat{\pmb{y}}^{(t-1)} \cdot \bar{\pmb{y}} 
ightharpoonup \text{concatenation} if \hat{\pmb{y}}^{(t)} \in L(\widehat{G}) then 
ho try parsing with \widehat{G}
                                                                      return \hat{\pmb{v}}^{(t)}
      7:
                                                                                                                                                               ⊳ if parsing fails, need to correct
      8:
                                                                       \boldsymbol{y}_{\text{prefix}}, \Sigma[\boldsymbol{y}_{\text{prefix}}] \leftarrow \text{EarleyParse}(\hat{\boldsymbol{y}}^{(t)}, \widehat{G})
     9:
                                                                        egin{align*} oldsymbol{w}^{s, \text{preiix}} & Earley & arset 
 10:
11:
12:
13: end while
```

with the full prompt and prefix along with the disallowed continuations, which is prohitively expensive.⁵

While there are many methods for grammar-constrained LM decoding [65, 62, 26], we present a simple strategy which speculatively decodes from the LLM to look ahead for multiple tokens. The pseudocode is shown in Algorithm 1. At each prediction step, we ask the LLM to speculatively decode the full program conditioned on the current prefix (lines 4-5). If the resulting continuation leads to a valid program, we return it (lines 6-7). Otherwise, we consult an Earley parser to extract the longest valid prefix from the current prediction (y_{prefix}), along with a set of valid terminals that can follow the prefix ($\Sigma[y_{\text{prefix}}]$). Finally, we rely on the LLM's probabilities to decide which terminal to use, with which a new partial program can be constructed (lines 10-11).⁶ Figure 3 illustrates one prediction step where the predicted program is corrected into a new valid partial program. Note that w can consist of multiple BPE tokens, e.g., "FindManager(" in Figure 3. By

⁴For example by using the logit_bias argument.

⁵These costs might be mitigated in the future if LLM APIs allow for cheaper use of cached prompts.

⁶In rare cases the set $\Sigma[y_{\text{prefix}}]$ was too large to feed to LLM APIs. In these cases we used Sentence-BERT [57] to compute the similarity between the encoding of $y_{\text{prefix}} \cdot w$ and $\hat{y}^{(t)}$ and took the top 16 candidates as $\Sigma[y_{\text{prefix}}]$.

Earley-based Constrained Decoding $\hat{\boldsymbol{y}}^{(t)}: \texttt{CreateEvent}(\& (\texttt{start}_? \texttt{Wednesday NumberPM}(3))(\texttt{attendee}_? \textit{Jean's Manager}))$ $Extract \ the \ longest \ valid \ prefix, \ and \ possible \ fixes \ (i.e., \ next \ terminals) \ based \ on \ Earley \ parsing: \ \boldsymbol{y}_{\text{prefix}}: \ \text{QueryEvent}(\& (\texttt{start}_? \texttt{Wednesday})(\texttt{attendee}_? \\ \Sigma[\boldsymbol{y}_{\text{prefix}}]: \ \{\textit{Jean , FindManager}(\} \}$ $Find \ the \ best \ candidate \ and \ concatenate \ it \ with \ the \ prefix: \ \hat{\boldsymbol{y}}_{(t)} \leftarrow \text{QueryEvent}(\& (\texttt{start}_? \texttt{Wednesday})(\texttt{attendee}_? \texttt{FindManager}())$

Figure 3: Illustration of how an predicted program is corrected in our proposed Earley-based constrained decoding. The final partial program will be subsequently fed into the LLM for continuation.

scoring over multi-token terminals, the search procedure is implicitly augmented by looking ahead for a few BPE tokens.

We use a similar procedure to operationalize the constraint $G' \subseteq G$, except that EarleyParse is constructed with a *metagrammar* (i.e., the grammar of G) for grammar prediction. See appendix A.1 for more details. In our ablation study we find that while these constraints are helpful insofar as they guarantee syntactic validity, grammar prompting still meaningfully improves upon standard prompting with even with simple unconstrained decoding.

4 Experiments

We apply grammar prompting to diverse domains: DSLs for semantic parsing (SMCalFlow, Overnight, GeoQuery), an action DSL (PDDL planning), and a molecule generation DSL (SMILES). These experiments are not necessarily intended to improve upon the state-of-the-art on these benchmarks but rather intended to assess whether LLMs can improve upon standard prompting for few-shot DSL generation by learning to predict and use grammars during in-context learning.

4.1 Semantic Parsing for Tool Usage

Software tools are typically accompanied by a collection of human-interpretable APIs which provide a platform for developers to interact programmatically with the tools. These APIs constitute a DSL, where each production rule of the grammar specifies the input and output types for a specific API call (see Figure 1 for an example). These tools demonstrate a broad spectrum in terms of DSL complexity, ranging from single-function tools such as Google(user_query), Translate(sentence, language) to more complex tools such as the entirety of Wolfram language. Enabling LLMs to use external tools via APIs is an important step towards enhancing their capabilities [61, 54, 51, 69, 45].

We test our approach on standard semantic parsing benchmarks involving complex DSLs: SM-CalFlow [6], which features human-generated utterances about calendar management (see Figure 2); GeoQuery [94] which features queries against a US Geography database; and Overnight-Blocks [77], which features queries about blocks in a synthetic block world. See appendix B for examples of input-output pairs along with the specialized grammars. The original benchmarks target the training of conventional semantic parsers and thus contain hundreds/thousands of training examples. We instead focus on the arguably more practical few-shot setting. Much existing LLM-based work on these benchmark rely on retrieval-based in-context learning which first retrieves m exemplars from a large training set of n examples ($n \gg m$) based on some similarity measure (e.g., BM-25), and then performs in-context learning with the retrieved exemplars [55, 90, 65, 44]. In contrast, we target the few-shot setting where we only assume access to 16–32 demonstration examples.

Our baselines here include: (1) standard prompting, (2) standard prompting with constrained decoding based on the full DSL grammar G [65, 62], and (3) a derivation tree-based prompting baseline which imbues more structural information to the exemplars by feeding the linearized derivation tree instead of the surface form program. We use Codex [12] as the base LLM for these main experiments. We assess methods according to program accuracy (matching the predicted and reference programs) as well as execution accuracy (same execution in both programs) if possible.

⁷https://www.wolfram.com/language/

⁸For example, the derivation tree of a subprogram (attendee_? FindManager(Jean)) is linearized to [constraint "(attendee_?" [attendee "FindManager(" [attendee "Jean" ")"] ")"], which uses square brackets to encode richer hierarchical information than just the surface form program.

	GeoQuery		SMCalFlow	Overni	ight-Blk
Approach	Prog.	Exec.	Prog.	Prog.	Exec.
Standard Prompting (unconstrained decoding)	60.7	81.5	46.4	29.3	54.7

Table 2: Results on retrieval-based in-context learning (left) and compositional generalization (right) with Codex. GeoQuery and Overnight-Blk show execution accuracy while SMCalFlow shows program accuracy. The numbers with ♠ and ♦ are taken from Ye et al. [90] and Cao et al. [10], respectively.

Few-Shot results. The main results are shown in Table 1. We find that grammar prompting can meaningfully improve upon the standard prompting baseline even without constrained decoding. Interestingly, grammar prompting outperforms derivation tree prompting which actually provides *more* information than the minimal specialized grammar G[y] (since the derivation tree explicitly shows how the rules are actually applied to obtain the program). This potentially indicates that having the LLM "plan out" the program by forcing it to predict the specialized grammar \widehat{G} first is an effective strategy. We also analyze the effect of constrained decoding on the number of LLM API calls in Table 7 of appendix A.1, where we observe that constrained decoding requires roughly three times more API calls than unconstrained decoding. Despite the promising performance of grammar prompting, there is a large gap between using the predicted grammar vs. using the oracle grammar (i.e., setting $\widehat{G} = G[y]$), indicating opportunities for further work in this area.

Retrieval-based in-context learning. While our core target application is few-shot semantic parsing, we also apply grammar prompting for retrieval-based in-context learning to test whether it can still improve performance in the data-rich regime and also to compare against the prior work on these benchmarks. Results in Table 2 (left) show that grammar prompting can improve results even in this setting, although the improvements are less pronounced than in the few-shot setting.

Out-of-distribution generalization. We experiment to see whether grammar prompting can improve compositional generalization on GeoQuery. Specifically, we test grammar prompting on the compositional splits of GeoQuery split from Shaw et al. [64]. These splits feature structural divergence between training and test examples, e.g., programs have different templates or length. Results in Table 2 (right) show that grammar prompting can improve upon standard prompting, across all splits (Template, TMCD, Length).

We next assess whether grammar prompting can enable LLMs to make zero-shot use of *unseen functions* (NewFunc) that are not even part of the retrieval set. We set aside 8 functions (smallest, shortest, most, highest, sum, population_1, count, major) and remove them from the retrieval set, simulating a scenario where new functions are supported in the backend yet no NL-program paired data is available for adapting a semantic parser. Note that for GeoQuery (and Overnight-Blk), we always prepend the full DSL grammar *G*—which includes the held-out functions—before the in-context exemplars. We observe that with standard prompting LLMs are still capable of guessing correct function names. However, grammar-prompted LLMs achieve significantly better performance than standard prompting, suggesting that the explicit prediction of specialized grammars elicits understanding and reasoning at the grammar level, thereby

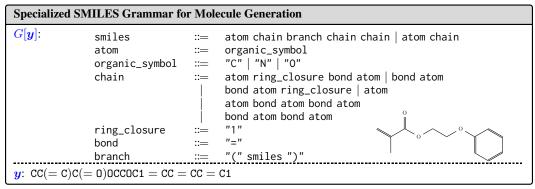

Figure 4: Example of a specialized grammar for generating a molecule from the Acrylates class.

enabling generalization to unseen functions. Finally, we found that without constrained generation, LLMs were often able to guess functions that did not exist but were nonetheless sensible. It would thus be interesting to explore whether LLMs can tackle DSL-open benchmarks such as LARC [1].

Different base LLMs. We finally experiment with grammar prompting across different base LLMs. Since GPT-3.5's 4K token limit is smaller than Codex's (8K) and GPT-4's (8K) limits, we use fewer exemplars in these experiments than before (24/8/16 exemplars for GeoQuery/SMCalFlow/Overnight-B respectively). Due to API cost, we limit our experiments to a smaller subset of 100 test examples instead of the full test set. In general we observe that grammar

LLM Variant	GeoQuery	SMCalFlow	Overnight-Blk
Standard + Codex	83	27	63
Grammar + Codex	95	35	66
Standard + GPT-3.5	75	9	49
Grammar + GPT-3.5	86	5	67
Standard + GPT-4	85	32	56
Grammar + GPT-4	98	36	62

Table 3: Results with different base LLMs on a subset of 100 examples sampled from the original test set. GeoQuery and Overnight-Blk show execution accuracy, while SMCalFlow shows program accuracy.

prompting can consistently improve upon standard prompting, except on SMCalFlow with GPT-3.5 where we observed both methods to perform poorly.

4.2 Class-Specific Molecule Generation

We next demonstrate that our approach works effectively beyond language parsing problems. We consider the molecule generation task, which is apparently a very domain-specific problem in which even LLMs may not have enough intrinsic expertise. Existing methods for molecule generation typically focus on training specialized neural models using large training sets [43, 36, 14, 2, 75, 59, 18]. We instead follow Guo et al. [29] and explore a few-shot setting where the task is to generate class-specific molecules given a small number of exemplars of that class. Formally, given a small set of molecules $\{y_c^{(i)}\}_{i=1}^N$ belonging to a particular molecule class $c \in \{\text{Acrylates}, \text{Chain Extenders}, \text{Isocyanates}\}$, our goal is to generate novel molecules y_c of the same class that can be synthesized using existing molecules. Since the in-context examples in this case will only consist of molecules of the same class, the "input" $x_c^{(i)}$ is the empty string in this case. The data contains 32 Acrylates, 11 Chain Extenders, and 11 Isocyanates (see appendix G of Guo et al. [29]).

While molecules can be more faithfully represented with 3D graph structure, the SMILES string representation [81] remains popular due to its ease of use. The specialized grammars $G[\boldsymbol{y}_c]$ (which are specialized from the SMILES grammar) encode various structural properties of the molecule that are specific to the molecule class. Figure 4 shows an example of a specialized grammar and the corresponding molecule in SMILES format. In this example, ring_closure ::= "1" specifies the number of rings, and branch ::= "(" smiles ")" specifies whether there is a branch.

We test our approach by generating 100 molecules for each class and assessing the quality of the generated molecules. In addition to the standard prompting baseline, we also run the graph grammar

⁹However SMILES does not guarantee that the generated string corresponds to a valid molecule. Using our approach on more advanced string representations such as SELFIES [42] (which guarantee validity) remains an interesting avenue for future work.

	Acrylates			Ch	Chain Extenders			Isocyanates				
Model	V	D	R	M	V	D	R	M	V	D	R	M
Graph Grammar [29]	100	0.83	79.0	30.3	100	0.86	72.7	98.3	100	0.93	52.2	82.7
Standard Prompting	87.7	0.73	80.0	76.7	60.3	0.89	72.7	55.7	94.7	0.82	78.0	92.2
Grammar Prompting	98.0	0.74	91.0	93.3	96.3	0.90	86.7	94.0	97.7	0.79	78.0	96.3

Table 4: Results for few-shot molecule generation with GPT-3.5. The metrics are validity (V), diversity (D), retrosynthesis score (R) and membership (M). Higher is better for all metrics.

baseline from Guo et al. [29] which learns hypergraph grammar [37] from the given molecules. We use four metrics: *Validity (V)*, the percentage of chemically valid molecules; *Diversity (D)*, average pairwise Tanimoto distance over Morgan fingerprints [58]; *Retrosynthesis score (R)*, the percentage of molecules that are synthesizable from existing molecules, which is computed approximately via the Retro* model [11]; *Membership (M)*, the percentage of molecules that belong to the desired monomer class. We use GPT-3.5 as the base LLM and sample from the LLM without constrained decoding, as constrained decoding was found to decrease the diversity of samples. See appendix A.2 for the full experimental setup.

Results. The results are presented in Table 4. We observe that grammar prompting significantly improves the synthesis of Acrylates and Chain Extenders across all metrics, while yielding mixed results for Isocyanates. Notably, both prompting-based methods outperform the graph grammar baseline in terms of Retro score, potentially due to the fact LLMs have been exposed to a certain number of existing molecules during pretraining, which proves advantageous for generating synthesizable molecules. In contrast, the baseline method cannot incorporate any external knowledge beyond the 11 or 32 molecules provided. While these results are preliminary, they potentially indicate that LLMs can serve as a useful tool for generating string representations of chemical structures (and potentially other biological/chemical structures), which remains underexplored.

4.3 Action Subset Selection for Efficient PDDL Planning

Our final experiments show how grammar prompting can improve the efficiency of classical AI planners. Classical planning is the problem of finding a sequence of actions (i.e., a plan) that goes from an initial state s_0 to a goal state s_g . An action is represented by a ground operator (e.g., unstack(block1, block2) which consists of an operator unstack along with two object arguments). We additionally consider *macro-operators* which can potentially speed up planning [8]. Planning tasks, along with actions, are represented in Planning Domain Definition Language (PDDL) [27]. We explore how grammar prompted LLMs can help guide classical planning algorithms.

We design specialized grammars to provide guidance to the classical greedy best-first search (GBFS) algorithm [5] by selecting a set of relevant actions. Figure 5 illustrates an example of such specialized grammar, which captures all the necessary actions for the final plan y that solves the given task. The process of the guided planning consists of the following steps: (1) given a task, predict a specialized grammar G[y]; (2) use the specialized grammar G[y] to subsequently generate a plan within the restricted action space derived from G[y]; (3) initialize GBFS's priority queue with the LLM-generated plan, and (4) search for the final plan in the restricted action space. Our setup builds upon the idea of using an LLM-generated plan to initialize GBFS from Silver et al. [66], which has a simpler two-step process: (1) given a task, predict a plan via standard prompting, and (2) utilize this plan to guide GBFS. We use their method as our baseline.

Following Silver et al. [66], we create a similar few-shot setting for LLM planning, using 5 tasks as in-context examples and 10 tasks for evaluation from Pyperplan [5]. We test our approach on 3 classic domains in PDDL planning, including Blocks, Depot and Satellite. For the action space, we use either a set of primitive actions (Prim) or an augmented set with macro actions (Macro). In addition to standard prompting, we add two more baselines: (1) No LLM: planning with the entire set of actions; (2) Min Macro: where we construct a minimal set of macro actions for each domain by selecting actions from existing plans for the training tasks. The Min Macro baseline is a domain-specific method to reduce the action space. By comparing to Min Macro, we can verify the effectiveness of instance-specific v.s. domain-specific action selection. See appendix A.3 for more details.

¹⁰For example, pickup-and-stack(A, B) is a combination of pickup(A) and stack(A, B).

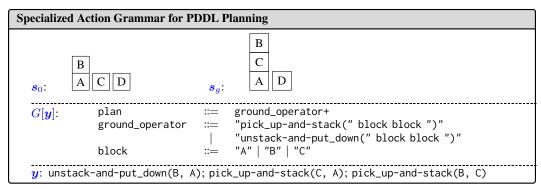

Figure 5: Example of a specialized grammar for PDDL planning in the Blocks domain. Given an input $x = (s_0, s_g)$, the specialized grammar G[y] only includes necessary actions for solving this task.

		Blocks			Depot			Satellite	
Approach	Created	Expanded	Success	Created	Expanded	Success	Created	Expanded	Success
GBFS + Prim. (No LLM)	360	188	1.0	18047	3870	0.4	8205	150	1.0
Standard + Prim. Grammar + Prim.	348 251	180 124	1.0 1.0	17597 15033	4039 3641	0.4 0.4	6686 5162	78 64	1.0 1.0
Standard + Macro. Grammar + Macro.	850 170	16 9	1.0 1.0	1460 2917	56 127	0.4 0.8	4003 3665	27 46	0.3 0.9
Standard + Min Macro.	228	8	1.0	1903	65	0.6	3483	35	0.8

Table 5: Results on PDDL planning. Created/Expanded refer to the number of created/expanded nodes during planning (lower is better). Success refers to success rate (higher is better). Numbers are averaged over three runs using GPT-3.5.

Results. We evaluate the efficiency of planning in terms of the number of search nodes created/expanded, as well as the success rate. Table 5 shows the promising performance of LLM-guided planning via grammar prompting. In Blocks, grammar prompting significantly improves efficiency while maintaining 100% success rate. In Depot, grammar prompting with macro actions increased the success rate by 20% over the best competing baseline. In Satellite, using primitive actions yields the best performance with 100% success rate and a reduction of 57% expanded nodes comparing to the No LLM baseline. While our experiments are not intended to complete with the state-of-the-art algorithms for fast planning [20–22, 31, 25, 78], they indicate the promise of LLMs for improving existing planning algorithms.

5 Discussion and Limitations

We discuss several limitations of our approach including some negative results. Grammar prompting did not yield any improvements for DSLs that were likely to have been frequently encountered during pretraining (e.g., regular expressions, SQL). Moreover, constrained generation based on specialized grammars led to increased API calls, and was not always beneficial for tasks beyond semantic parsing. For instance, in molecule generation we discovered that enforcing constraints can sometimes result in worse performance, suggesting that while intermediate grammar may aid reasoning, the predictions remain imperfect. Additionally, in PDDL planning we observed that the constraints applied to prune objects can sometimes negatively impact performance, suggesting that relevant object selection is still very challenging for LLMs. It may be interesting to explore whether finetuning of moderately-sized LLMs using specialized grammars can lead to better grammar-based models for DSL generation.

On the positive front, our work demonstrates that LLMs have the capacity to understand and generate metalanguages. Working in this "metalanguage space" can be combined with chain-of-thought-style [80] prompts by, for example, manually providing natural language comments to the rules of the specialized grammars. We found this to improve results slightly on semantic parsing (see Figure 6 of appendix A.1). Many scientific problems can be formally approached by representing hypotheses into DSL programs [68]. Similarly, DSLs can enable easier encoding of human prior knowledge and scientific principles, providing a foundation for scientific discovery. Recent work shows that state-of-the-art LLMs can follow previously unseen formal systems [72]. Techniques like grammar prompting can widen the scope of scientific problems for which LLMs could be effectively applied by more explicitly accounting for external knowledge and constraints.

6 Related Work

Chain-of-thought prompting. Grammar prompting extends the recent line of work on improving the reasoning capabilities through providing explicit reasoning steps as part of the prompt [49, 24, 80, 76, 13, 89]. Our approach is closely related to much concurrent work on employing symbolic variables as part of the prompt [30, 48, 32, 92, 50], though to our knowledge we are not aware of any works that use formal grammars as the intermediate reasoning step.

LLMs for program generation and semantic parsing. Generating programs from natural language specifications, a task often referred to as semantic parsing in the NLP community, is a sub-problem of program synthesis where specifications can come in various forms, including input-output examples; for surveys, see Kamath and Das [38] and Gulwani et al. [28]. Recent works [7, 83] have explored using LLMs for generating code in general-purpose programming languages (e.g., Python) given natural language descriptions. Our work further extends this line by examining whether LLM can generate DSL programs, which are intrinsically scarce. Moreover, DSLs evolve much more rapidly, with API functions being frequently added, changed, or deleted according to tool development or user requirements. Grammar prompting provides a straightforward strategy for LLMs to improve DSL program generation even when only a limited set of examples is available.

Recent studies have begun investigating the use of LLMs for DSL generation. For tools with simple DSLs, such as a search function on Google/Bing, a calculator or a ToDo listing, the current ChatGPT Plugin¹¹ is hypothesized to operate as a zero-shot/few-shot semantic parser. Toolformer [61] goes a step further by training an LLM to learn the appropriate context and usage for these simple-DSL tools. More recent work has explored few-shot prompting along with API descriptions for a broader array of tools Qin et al. [54], including for multimodal reasoning [82, 69, 88]. In contrast, our study focuses on domains that necessitate a more complex DSL and consequently require a greater reasoning capacity from the LLM. Other works focus on investigating how model scales [55] and retrievers [91, 44] affect in-context learning. There has also been work on grammar-constrained decoding with LLMs for semantic parsing [62, 65, 53], which serves as baselines in our empirical study.

Neural grammars. Grammar prompting can also been seen as a "fully LLM" instantiation of the line of work on neural parameterizations of symbolic grammars [34, 16, 41, 40, 35, 95, 86, 85, 87]. Indeed, our approach to semantic parsing essentially uses prompt-based learning to define a quasi-synchronous grammar [67, 74] whose rules dynamically depend on the source sentence. Concretely, in contrast to recent works which embed learnable neural components within synchronous grammars [39, 23, 73], grammar prompting relies on the implicit in-context learning capabilities of LLMs for the learning component.

Grammar-based molecule generation. Grammar-based methods have gained significant interest in the realm of molecule generation, offering advantages in interpretability, data-efficiency, and controllability. One line of research involves integrating generic SMILES grammars with neural networks to generate syntactically meaningful molecules [43, 14]. Another approach centers on data-driven induction of grammars for generation [29, 37]. Our work aligns with the former, viewing grammar prompting as a straightforward method of integrating grammar into an LLM without the need for additional training.

LLMs for planning. Recently, LLMs have increasingly been utilized for planning in embodied agents, given their potential for extensive world knowledge and strong reasoning abilities. When given goals expressed in natural language in household environments, earlier work [3, 63, 33, 46] directly prompted LLMs to sequence executable actions. However, in PDDL domains, where the desired action sequences are much longer, recent work [66, 71] has found LLMs to underperform classical planners in PDDL planning. Grammar prompting represents a promising strategy for augmenting existing planners with LLMs. Future work could further integrate LLMs with planning by exploiting more reasoning capacities from LLMs in addition to existing efforts such as translating between problems and PDDL models [47], corrective re-prompting [56]. This might involve inducing action models [4], macro-actions [8], sub-tasks [19] or generalized planning [84].

7 Conclusion

We propose grammar prompting as a simple approach for improving the few-shot DSL generation with large language models. Experiments across a range of structured languages including DSLs for semantic parsing (SMCalFlow, GeoQuery, Overnight), PDDL planning (action DSL), and molecule generation (SMILES), show that grammar prompting can improve upon standard prompting baselines. The encouraging results in semantic parsing indicate its potential to assist LLMs with tool usage, and the promising results in other domains indicate that grammar prompting can enable application of LLMs in domains that intrinsically depend on DSLs.

w. grammar and program constraint $(\widehat{m{y}} \in L(\widehat{G}))$	88.9 (3.3)	52.4 (3.3)	60.9 (2.8)
w. oracle grammar ($\widehat{G}=G[m{y}]$) w. oracle grammar + program constraint	96.1 (1.3) 96.8 (2.1)	80.0 (1.0) 83.6 (2.6)	94.2 (1.0) 96.5 (1.0)

Table 7: Extended results which show the number of Codex calls per example on few-shot semantic parsing in brackets. Columns in grey show program accuracy, while white columns others indicate execution accuracy.

A Experiment Details

A.1 Semantic Parsing

Statistics and Splits. We show the statistics for the splits used for the experiments in Table 6.

For GeoQuery, we utilize the standard split from Zelle and Mooney [94] in the retrieval-based setting and the Template, TMCD, and Length splits from Shaw et al. [64]. We randomly sample 32 examples from the training set of the standard split to create the few-shot split. To generate the NewFunc split, we designate examples utilizing the following eight functions as test examples: smallest, shortest, most, highest, sum, population_1, count, major; the remaining examples are incorporated into the training set.

For SMCalFlow, we adopt the 16-shot and 128-shot cross-domain settings from Yin et al. [93] as our few-shot and retrieval-based settings, respectively. It is noteworthy that the training set of the original splits contains approximately 25k in-domain training examples. Previous work [91, 55] utilized these examples as their retrieval set. However, in our experiments, we found that incorporating in-domain examples did not enhance performance. Consequently, we use 16/128 cross-domain examples as our training set in the few-shot and retrieval settings, respectively. For all experiments on SMCalFlow, we used the preprocessed version from Qiu et al. [55], which employs a more concise LISPRESS format [52] than the original version [93]. This format aligns with Ye et al. [91] for a fair comparison.

For Overnight-Blocks, we employ the standard split from Wang et al. [77] in the retrieval setting. We randomly sample 32 examples from the training set of the standard split to create the few-shot split.

Scoring Functions for Constrained Generation. For each candidate continuation $w \in \Sigma[y_{\text{prefix}}]$ for correction, we first form a partial program via concatenation $y_{\text{prefix}} \cdot w$ and then feed it into Codex to obtain the score for the candidate via

$$\log P_{\text{LLM}}(\boldsymbol{w} \mid \widehat{G}, \boldsymbol{x}, \boldsymbol{y}_{\text{prefix}}, (\boldsymbol{x}^{(i)}, G[\boldsymbol{y}^{(i)}], \boldsymbol{y}^{(i)})_{i=1}^{N}).$$

In the case where w consists of multiple BPE tokens, e.g., FindManger(is tokenized into Find, Manager, and (, we average the token-level log-likelihood to obtain a candidate-level score. However, when the size of $\Sigma[y_{\text{prefix}}]$ exceeds 16, invoking Codex for each candidate becomes too expensive. To address this issue, we employ SentenceBERT to select 16 most plausible candidates first via a dot product,

$$(SentenceBERT(\hat{y}_t))^{\top}(SentenceBERT(y_{prefix} \cdot w)),$$

where SentenceBERT yields the embeddings for the incorrect prediction \hat{y}_t and a candidate of corrected partial program $y_{\text{prefix}} \cdot w$.

Molecule Class	Temperature	Presence Penalty	Frequency Penalty
Sampling specialized grammars \widehat{G}			
Acrylates	0.6	0.1	0.1
Chain Extenders	0.6	0.1	0.1
Isocyanates	0.6	0.4	0.4
Sampling molecules $\widehat{m{y}}$			
Acrylates	0.6	0.1	0.1
Chain Extenders	0.6	0.1	0.1
Isocyanates	0.3	0.4	0.4

Table 8: Hyperparameters for sampling specialized grammars \widehat{G} (top) and the molecules \widehat{y} in grammar prompting for molecule generation. Standard prompting uses the same hyperparameters for y.

The functionality of obtaining the log-likelihood for a candidate continuation given a prefix is applicable via Codex APIs ¹² via setting logprobs=True and echo=True. Unfortunately, subsequent models (e.g., GPT-3.5 and GPT-4) disable such functionality. As a workaround, we simply use the scoring function based on SentenceBERT to directly select the best candidate in our PDDL planning experiments.

Cost Efficiency. We assess various decoding strategies for their cost efficiency, focusing on the number of API calls. The number of Codex calls resulting from the few-shot semantic parsing experiments is presented in Figure 7, alongside the corresponding accuracy metrics. The results indicate that standard prompting under constrained decoding leads to a significantly higher number of Codex calls. Similarly, grammar-prompting with constraints also results in an increased number of Codex calls. However, when employing both grammar and program constraints, the number of calls decreases meaningfully in comparison to standard prompting under constrained decoding. Future work might consider exploring strategies for more cost-efficient constrained decoding.

Grammar Prompting with Annotated Rules. We have additionally experimented with enhancing BNF rules by appending natural language comments. As illustrated in Figure 6, we pair each BNF rule with its corresponding natural language phrases extracted from the given query x. These manually annotated comments yield an explicit correspondence between natural language phrases and their corresponding BNF rules, thereby better facilitating interpretation and application of the grammars for generating programs. When employing the augmented grammar prompting, we noticed marginal improvements on SMCalFlow (+1.0%) and Overnight-Blocks (0.5%), with no observed enhancement on GeoQuery. While the gains might not appear significant, this predicted alignment could potentially contribute to improved interpretability and further constraints on generation. For instance, the phrase "someone's manager" should consistently trigger the function FindManager (. We leave the exploration of utilizing the augmented rules for future work.

A.2 Molecule Generation

Sampling Procedure Different from semantic parsing and PDDL planning, where the most probable program y needs to be found via arg max inference, molecule generation has empty specification x and requires sampling from a prompting-based distribution. The sampling procedure for grammar prompting consists of three stages: (1) we randomly sample a permutation of given molecules, denoted as π , (2) based on a prompt formed by the permutation, we sample a specialized grammar \hat{G} via

$$\widehat{G} \sim P_{\text{LLM}}(G' \,|\, \boldsymbol{x}, (G[\boldsymbol{y}^{(\pi[i])}], \boldsymbol{y}^{(\pi[i])})_{i=1}^N),$$

iii) we finally obtain the molecule conditioned \widehat{G} ,

$$\widehat{\boldsymbol{y}} \sim P_{\text{LLM}}(\boldsymbol{y} \,|\, \widehat{G}, (G[\boldsymbol{y}^{(\pi[i])}], \boldsymbol{y}^{(\pi[i])})_{i=1}^{N}).$$

We list the hyperparameters used for the sampling procedure in for (2) in Table 8 (top) and for (3) in Table 8 (bottom).

                                                                         with ...
                               "Wednesday"
                                                                         Wednesday
           date
                               "NumberPM(3)"
           time
                         ::=
                                                                         3PM
                               "FindManager(" attendee ")" | "Jean"
                                                                        Jean's manager
           attendee
                         ::=
\hat{y}: CreateEvent(& (start_? Wednesday NumberPM(3))(attendee_? FindManager(Jean)))
```

Figure 6: Example of grammar prompting where BNF grammars are additionally annotated with natural language comments (shown in green). These manually curated comments provide a detailed mapping between natural language phrases and their corresponding BNF rules, thereby better facilitating interpretation and application of the grammars for generating programs. We manually craft and add these comments to the few-shot prompts (top). The model predicts this during inference (bottom).

In comparison, the sampling procedure for standard prompting only consists of two stages: (1) we randomly sample a permutation of given molecules, denoted as π , (2) based on a prompt formed by the permutation, we directly sample a molecule via

$$\widehat{\boldsymbol{y}} \sim P_{\text{LLM}}(\boldsymbol{y} \mid (\boldsymbol{y}^{(\pi[i])})_{i=1}^{N}).$$

The hyperparameters used for Step (2) is the same as in grammar prompting and shown in Table 8 (bottom).

While we observed that Earley-based constrained generation enhances grammar prompting in terms of improving validity, other metrics, such as the retrosynthesis score, decreased significantly. This discrepancy could be attributed to the fact that existing LLMs, due to their limited exposure to molecules represented in SMILES format, struggle with comprehending and applying the BNF grammar rules of SMILES. Overall, our current findings serve as preliminary evidence that grammar prompting can tap into the capacity of LLMs to understand and apply BNF rules. However such capacity still remains limited in text-focused LLMs.

A.3 PDDL Planning

Restricted Action Space The specialized grammar defined for PDDL planning essentially delineates a constrained action space that includes necessary actions and their associated objects. Our empirical results found that limiting the classical GBFS planner to the objects selected by a specialized grammar proved too restrictive, yielding beneficial results only within the Blocks domain. Therefore, we decided to remove this limitation, thus expanding the action space of GBFS to contain the actions predicted from the grammar with an unrestricted range of objects.

B Prompts

Figures 7, 8, and 9 demonstrate the prompts with grammars, based on actual examples in the SM-CalFlow, GeoQuery, and Overnight datasets respectively. Because the general grammar of SM-CalFlow is long (around 4k tokens), we do not include it within the prompt. For GeoQuery and Overnight, the general grammar is integrated as part of the instruction within the prompt. In the context of molecule generation, the general grammar for SMILES¹³ is also included. For PDDL planning, considering the simplicity of the action DSL, the general grammar is not deemed necessary for inclusion.

```
You are an expert programmer, and you need to write a program for the given natural language query.
First, you should write grammar rules by choosing from the following BNF rules. Then, you should write
programs that conform to your predicted rules.
[BEGIN RULES]
                                     "answer(" answer_type ")"
                query
                               ::=
                                     \verb|city| | \verb|state| | \verb|num| | \verb|place| | \verb|river| | \verb|country||
                answer_type
                              ::=
                                     "city(" city ")"
                city
                               ::=
                                     "cityid('" CITYNAME "', '" STATEABBREV "')"
                                      "cityid('" CITYNAME "', _)"
                                     "capital(" city ")"
"major(" city ")"
"capital_1(" state ")"
                                     "loc_2(" state ")"
"loc_2(" country ")"
                                     "largest(" city ")"
                                     "smallest(" city ")"
                                      "intersection(" city "," city ")"
                                      "exclude(" city "," city ")"
